```

Mathematics (2)

2.1 Equations

$$ax + by = e \atop cx + dy = f \Rightarrow \begin{array}{l} x = \dfrac{ed - bf}{ad - bc} \\ y = \dfrac{af - ec}{ad - bc} \end{array}$$

Cramer's Rule: given an equation $Ax = b$, the solution to a variable x_i is given by

$$x_i = \frac{\det A'_i}{\det A}$$

where A'_i is A with the i'th column replaced by b.

2.2 Recurrences

If $a_n = c_1 a_{n-1} + \cdots + c_k a_{n-k}$, and $r_1, \ldots, r_k$ are distinct roots of $x^k + c_1 x^{k-1} + \cdots + c_k$, there are $d_1, \ldots, d_k$ s.t.

$$a_n = d_1 r_1^n + \cdots + d_k r_k^n.$$

Non-distinct roots r become polynomial factors, e.g. $a_n = (d_1 n + d_2) r^n$.

2.3 Trigonometry

$$\sin(v + w) = \sin v \cos w + \cos v \sin w$$
$$\cos(v + w) = \cos v \cos w - \sin v \sin w$$
$$\tan(v + w) = \frac{\tan v + \tan w}{1 - \tan v \tan w}$$
$$\sin v + \sin w = 2 \sin \frac{v + w}{2} \cos \frac{v - w}{2}$$
$$\cos v + \cos w = 2 \cos \frac{v + w}{2} \cos \frac{v - w}{2}$$

$$a \cos x + b \sin x = r \cos(x - \phi)$$
$$a \sin x + b \cos x = r \sin(x + \phi)$$

where $r = \sqrt{a^2 + b^2}, \phi = \operatorname{atan2}(b, a)$.

2.4 Geometry
2.4.1 Triangles
Side lengths: a, b, c

Semiperimeter: $s = \dfrac{a + b + c}{2}$

Area: $A = \sqrt{s(s - a)(s - b)(s - c)}$

Circumradius: $R = \dfrac{abc}{4A}$

Inradius: $r = \dfrac{A}{p}$

Length of median (divides triangle into two equal-area triangles):
$m_a = \frac{1}{2}\sqrt{2b^2 + 2c^2 - a^2}$
Length of bisector (divides angles in two):

$$s_a = \sqrt{bc \left[1 - \left(\frac{a}{b + c}\right)^2\right]}$$

Law of sines: $\dfrac{\sin \alpha}{a} = \dfrac{\sin \beta}{b} = \dfrac{\sin \gamma}{c} = \dfrac{1}{2R}$

Law of cosines: $a^2 = b^2 + c^2 - 2bc \cos \alpha$

Law of tangents: $\dfrac{a + b}{a - b} = \dfrac{\tan \dfrac{\alpha + \beta}{2}}{\tan \dfrac{\alpha - \beta}{2}}$
2.4.2 Quadrilaterals
With side lengths a, b, c, d, diagonals e, f, diagonals angle θ, area A and magic flux $F = b^2 + d^2 - a^2 - c^2$:

$$4A = 2ef \cdot \sin \theta = F \tan \theta = \sqrt{4e^2 f^2 - F^2}$$

For cyclic quadrilaterals the sum of opposite angles is $180°$, $ef = ac + bd$, and $A = \sqrt{(s - a)(s - b)(s - c)(s - d)}$.

2.4.3 Spherical coordinates

$$x = r\sin\theta\cos\phi \qquad r = \sqrt{x^2 + y^2 + z^2}$$
$$y = r\sin\theta\sin\phi \qquad \theta = \mathrm{acos}(z/\sqrt{x^2 + y^2 + z^2})$$
$$z = r\cos\theta \qquad \phi = \mathrm{atan2}(y, x)$$

2.5 Derivatives/Integrals

$$\frac{d}{dx}\arcsin x = \frac{1}{\sqrt{1 - x^2}} \qquad \frac{d}{dx}\arccos x = -\frac{1}{\sqrt{1 - x^2}}$$

$$\frac{d}{dx}\tan x = 1 + \tan^2 x \qquad \frac{d}{dx}\arctan x = \frac{1}{1 + x^2}$$

$$\int \tan ax = -\frac{\ln|\cos ax|}{a} \qquad \int x\sin ax = \frac{\sin ax - ax\cos ax}{a^2}$$

$$\int e^{-x^2} = \frac{\sqrt{\pi}}{2}\mathrm{erf}(x) \qquad \int xe^{ax}dx = \frac{e^{ax}}{a^2}(ax - 1)$$

Integration by parts:

$$\int_a^b f(x)g(x)dx = [F(x)g(x)]_a^b - \int_a^b F(x)g'(x)dx$$

2.6 Sums/Series

$$\ln(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \ldots, \ (-1 < x \le 1)$$

$$\sqrt{1 + x} = 1 + \frac{x}{2} - \frac{x^2}{8} + \frac{2x^3}{32} - \frac{5x^4}{128} + \ldots, \ (-1 \le x \le 1)$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \ldots, \ (-\infty < x < \infty)$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \ldots, \ (-\infty < x < \infty)$$

2.7 Probability theory

Let X be a discrete random variable with probability $p_X(x)$ of assuming the value x. It will then have an expected value (mean) $\mu = \mathbb{E}(X) = \sum_x x p_X(x)$ and variance $\sigma^2 = V(X) = \mathbb{E}(X^2) - (\mathbb{E}(X))^2 = \sum_x (x - \mathbb{E}(X))^2 p_X(x)$ where σ is the standard deviation.

$$\mathbb{E}(aX + bY) = a\mathbb{E}(X) + b\mathbb{E}(Y)$$

If X, Y are independent,

$$V(aX + bY) = a^2 V(X) + b^2 V(Y).$$

Expectation is linear If X is instead continuous it will have a probability density function $f_X(x)$ and the sums above will instead be integrals with $p_X(x)$ replaced by $f_X(x)$.

2.7.1 Discrete distributions
Binomial distribution

\# of successes in n independent yes/no experiments, each which yields success with probability p is
$\mathrm{Bin}(n, p)$, $n = 1, 2, \ldots, 0 \le p \le 1$.

$$p(k) = \binom{n}{k} p^k (1 - p)^{n-k}$$

$$\mu = np, \ \sigma^2 = np(1 - p)$$

$\mathrm{Bin}(n, p) \approx \mathrm{Po}(np)$ for small p.

First success distribution

The number of trials needed to get the first success in independent yes/no experiments, each wich yields success with probability p is $\mathrm{Fs}(p)$, $0 \le p \le 1$.

$$p(k) = p(1 - p)^{k-1}, \ k = 1, 2, \ldots$$

$$\mu = \frac{1}{p}, \ \sigma^2 = \frac{1 - p}{p^2}$$

Poisson distribution

The number of events occurring in a fixed period of time t if these events occur with a known average rate κ and independently of the time since the last event is $\mathrm{Po}(\lambda)$, $\lambda = t\kappa$.

$$p(k) = e^{-\lambda}\frac{\lambda^k}{k!}, k = 0, 1, 2, \ldots$$

$$\mu = \lambda, \ \sigma^2 = \lambda$$

$\mathrm{Bin}(n, p) \approx \mathrm{Po}(np)$ for small p (binomial distribution with n coin flips, each of which is heads with probability p).

2.7.2 Continuous distributions
Uniform distribution

If the probability density function is constant between a and b and 0 elsewhere it is $\mathrm{U}(a, b)$, $a < b$.

$$f(x) = \begin{cases} \frac{1}{b-a} & a < x < b \\ 0 & \text{otherwise} \end{cases}$$

$$\mu = \frac{a + b}{2}, \ \sigma^2 = \frac{(b - a)^2}{12}$$

Exponential distribution

The time between events in a Poisson process is $\mathrm{Exp}(\lambda)$, $\lambda > 0$.

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & x \ge 0 \\ 0 & x < 0 \end{cases}$$

$$\mu = \frac{1}{\lambda}, \ \sigma^2 = \frac{1}{\lambda^2}$$

Normal distribution

Most real random values with mean μ and variance σ^2 are well described by $\mathcal{N}(\mu, \sigma^2)$, $\sigma > 0$.

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

If $X_1 \sim \mathcal{N}(\mu_1, \sigma_1^2)$ and $X_2 \sim \mathcal{N}(\mu_2, \sigma_2^2)$ then

$$aX_1 + bX_2 + c \sim \mathcal{N}(\mu_1 + \mu_2 + c, a^2\sigma_1^2 + b^2\sigma_2^2)$$

Data Structures (3)

3.1 STL

HashMap.h
Description: Hash map with similar API as unordered_map. Initial capacity must be a power of 2 if provided.
Usage: `ht<int,int> h({},{},{},{},{1<<16});`
Memory: ~1.5x unordered map
Time: ~3x faster than unordered map
`<ext/pb_ds/assoc_container.hpp>`   5872b2, 9 lines

```
using namespace __gnu_pbds;
struct chash {
  const uint64_t C = ll(4e18*acos(0))+71; // large odd number
  const int RANDOM = rng();
  ll operator()(ll x) const { return __builtin_bswap64((x^
    ↪RANDOM)*C); }
};
template<class K,class V> using ht = gp_hash_table<K,V,chash>;
template<class K,class V> V get(ht<K,V>& u, K x) {
  auto it = u.find(x); return it == end(u) ? 0 : it->s; }
```

OrderStatisticTree.h
Description: A set (not multiset!) with support for finding the n'th element, and finding the index of an element. Change null_type to get a map.
Time: $\mathcal{O}(\log N)$
`<ext/pb_ds/assoc_container.hpp>`   018476, 5 lines

```
using namespace __gnu_pbds;
tcT> using Tree = tree<T, null_type, less<T>,
  rb_tree_tag, tree_order_statistics_node_update>;
#define ook order_of_key
#define fbo find_by_order
```

LineContainer.h
Description: Add lines of the form $ax + b$, query maximum y-coordinate for any x.
Time: $\mathcal{O}(\log N)$

<div align="right">df7386, 29 lines</div>

```cpp
using T = ll; const T INF = LLONG_MAX; // a/b rounded down
// ll fdiv(ll a, ll b) { return a/b-((a^b)<0&&a%b); }

bool _Q = 0;
struct Line {
  T a, b; mutable T lst;
  T eval(T x) const { return a*x+b; }
  bool operator<(const Line&o)const{return _Q?lst<o.lst:a<o.a;}
  T last_gre(const Line& o) const { assert(a <= o.a);
    // greatest x s.t. a*x+b >= o.a*x+o.b
    return lst=(a==o.a?(b>=o.b?INF:-INF):fdiv(b-o.b,o.a-a));}
};

struct LineContainer: multiset<Line> {
  bool isect(iterator it) { auto n_it = next(it);
    if (n_it == end()) return it->lst = INF, 0;
    return it->last_gre(*n_it) >= n_it->lst; }
  void add(T a, T b) {
    auto it = ins({a,b,0}); while (isect(it)) erase(next(it));
    if (it == begin()) return;
    if (isect(--it)) erase(next(it)), isect(it);
    while (it != begin()) {
      --it; if (it->lst < next(it)->lst) break;
      erase(next(it)); isect(it); }
  }
  T qmax(T x) { assert(!empty());
    _Q = 1; T res = lb({0,0,x})->eval(x); _Q = 0;
    return res; }
};
```

Bset.h
Description: bitset of variable size. Careful since it's slower than std::bitset
Usage: tr2::dynamic_bitset<> bs;
bs.is_subset_of(), bs.is_proper_subset_of(), bs.find_first(),
bs.find_next(pos)
<tr2/dynamic_bitset>

3.2   1D Range Queries

RMQ.h
Description: 1D range minimum query. If TL is an issue, use arrays instead of vectors and store values instead of indices.
Memory: $\mathcal{O}(N \log N)$
Time: $\mathcal{O}(1)$
"template.hpp"

<div align="right">a3f881, 19 lines</div>

```cpp
tcT> struct RMQ { // floor(log_2(x))
  int level(int x) { return 31-__builtin_clz(x); }
  V<T> v; V<vi> jmp;
  int cmb(int a, int b) {
    return v[a]==v[b]?min(a,b):(v[a]<v[b]?a:b); }
  void init(const V<T>& _v) {
    v = _v; jmp = {vi(sz(v))};
    iota(all(jmp[0]),0);
    for (int j = 1; 1<<j <= sz(v); ++j) {
      jmp.pb(vi(sz(v)-(1<<j)+1));
      F0R(i,sz(jmp[j])) jmp[j][i] = cmb(jmp[j-1][i],
        jmp[j-1][i+(1<<(j-1))]);
    }
  }
  int index(int l, int r) {
    assert(l <= r); int d = level(r-l+1);
    return cmb(jmp[d][l], jmp[d][r-(1<<d)+1]); }
  T query(int l, int r) { return v[index(l,r)]; }
};
```

BIT.h
Description: Computes partial sums a[0] + a[1] + ... + a[pos - 1], and updates single elements a[i], taking the difference between the old and new value.
Time: Both operations are $\mathcal{O}(\log N)$.

<div align="right">b183a2, 17 lines</div>

```cpp
tcT> struct BIT {
  int N; V<T> data;
  void init(int _N) { N = _N; data.rsz(N); }
  void add(int p, T x) { for (++p;p<=N;p+=p&-p) data[p-1] += x;
    ↪ }
  T sum(int l, int r) { return sum(r+1)-sum(l); }
  T sum(int r) { T s = 0; for(;r;r-=r&-r)s+=data[r-1]; return s
    ↪; }
  int lower_bound(T sum) {
    if (sum <= 0) return -1;
    int pos = 0;
    for (int pw = 1<<25; pw; pw >>= 1) {
      int npos = pos+pw;
      if (npos <= N && data[npos-1] < sum)
        pos = npos, sum -= data[pos-1];
    }
    return pos;
  }
};
```

LazySegTree.h
Description: Segment Tree with lazy updates. Segments are [l,r)
Time: $\mathcal{O}(\log N)$ per query
"template.hpp"

<div align="right">ad3fad, 75 lines</div>

```cpp
template<typename T, typename E, T (*f)(T, T), T (*g)(T, E), E
  ↪(*h)(E, E), T(*ti)(), E (*ei)()>

  }
};
```

Order.h
Description: Calculates smallest P such that $x^P \equiv 1 \mod p$
<div align="right">"ModMulLL.h", "FactorBasic.h"   e2c3b7, 7 lines</div>

```
ll order(ll x, ll p) {
  if (gcd(x,p) != 1) return 0;
  ll P = phi(p); auto a = factor(P);
  each(t,a) while (P % t.f == 0
    && modPow(x,P/t.f,p) == 1) P /= t.f;
  return P;
}
```

4.2 Primality

4.2.1 Primes

$p = 962592769$ is such that $2^{21} \mid p - 1$, which may be useful. For hashing use 970592641 (31-bit number), 31443539979727 (45-bit), 3006703054056749 (52-bit). There are 78498 primes less than $1\,000\,000$.

Primitive roots exist modulo any prime power p^a, except for $p = 2, a > 2$, and there are $\phi(\phi(p^a))$ many. For $p = 2, a > 2$, the group $\mathbb{Z}_{2^a}^{\times}$ is instead isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_{2^{a-2}}$.

4.2.2 Divisors
$\sum_{d|n} d = O(n \log \log n)$.

The number of divisors of n is at most around 100 for $n < 5e4$, 500 for $n < 1e7$, 2000 for $n < 1e10$, $200\,000$ for $n < 1e19$.

Dirichlet Convolution: Given a function $f(x)$, let

$$(f * g)(x) = \sum_{d|x} g(d) f(x/d).$$

If the partial sums $s_{f*g}(n), s_g(n)$ can be computed in $O(1)$ and $s_f(1 \ldots n^{2/3})$ can be computed in $O\left(n^{2/3}\right)$ then all $s_f\left(\frac{n}{d}\right)$ can as well. Use

$$s_{f*g}(n) = \sum_{d=1}^{n} g(d) s_f(n/d).$$

If $f(x) = \mu(x)$ then $g(x) = 1, (f * g)(x) = (x == 1)$, and $s_f(n) = 1 - \sum_{i=2}^{n} s_f(n/i)$.

If $f(x) = \phi(x)$ then $g(x) = 1, (f * g)(x) = x$, and $s_f(n) = \frac{n(n+1)}{2} - \sum_{i=2}^{n} s_f(n/i)$.

Sieve.h
Description: Tests primality up to SZ. Runs faster if only odd indices are stored.
Time: $\mathcal{O}(SZ \log \log SZ)$ or $\mathcal{O}(SZ)$
<div align="right">41c6ed, 20 lines</div>

```
template<int SZ> struct Sieve {
  bitset<SZ> is_prime; vi primes;
  Sieve() {
    is_prime.set(); is_prime[0] = is_prime[1] = 0;

  // now minimize A*x-new_B*y+C
  // where 0 <= x,y and x+q*y <= M, 0 <= C < new_B < A
  // q*y -> C-new_B*y
  if (C/new_B > M/q) return C-M/q*new_B;
  M -= C/new_B*q; C %= new_B; // now C < new_B

  // given y, we can compute x = ceil[((B-q*A)*y-C)/A]
  // so x+q*y = ceil((B*y-C)/A) <= M
  ll max_Y = (M*A+C)/B; // must have y <= max_Y
  ll max_X = cdiv(new_B*max_Y-C,A); // must have x <= max_X
  if (max_X*A-new_B*max_Y+C >= new_B) --max_X;
  // now we can remove upper bound on y
  return minRemainder(A,new_B,C,max_X);
}
```

4.4 Pythagorean Triples

The Pythagorean triples are uniquely generated by

$$a = k \cdot (m^2 - n^2), \ b = k \cdot (2mn), \ c = k \cdot (m^2 + n^2),$$

with $m > n > 0$, $k > 0$, $m \perp n$, and either m or n even.

4.5 Lifting the Exponent

For $n > 0$, p prime, and ints x, y s.t. $p \nmid x, y$ and $p | x - y$:

- $p \neq 2$ or $p = 2, 4 | x - y \implies v_p(x^n - y^n) = v_p(x - y) + v_p(n)$.

- $p = 2, 2 | n \implies v_2(x^n - y^n) = v_2((x^2)^{n/2} - (y^2)^{n/2})$.

Combinatorial (5)

5.1 Permutations

5.1.1 Cycles

Let $g_S(n)$ be the number of n-permutations whose cycle lengths all belong to the set S. Then

$$\sum_{n=0}^{\infty} g_S(n) \frac{x^n}{n!} = \exp\left(\sum_{n \in S} \frac{x^n}{n}\right)$$

5.1.2 Burnside's lemma

Given a group G of symmetries and a set X, the number of elements of X *up to symmetry* equals

$$\frac{1}{|G|} \sum_{g \in G} |X^g|,$$

where X^g are the elements fixed by g ($g.x = x$).

If $f(n)$ counts "configurations" (of some sort) of length n, we can ignore rotational symmetry using $G = \mathbb{Z}_n$ to get

$$g(n) = \frac{1}{n} \sum_{k=0}^{n-1} f(\gcd(n, k)) = \frac{1}{n} \sum_{k|n} f(k)\phi(n/k).$$

5.2 Partitions and subsets

5.2.1 Partition function

Number of ways of writing n as a sum of positive integers, disregarding the order of the summands.

$$p(0) = 1, \ p(n) = \sum_{k \in \mathbb{Z}\setminus\{0\}} (-1)^{k+1} p(n - k(3k - 1)/2)$$

$$p(n) \sim 0.145/n \cdot \exp(2.56\sqrt{n})$$

n	0	1	2	3	4	5	6	7	8	9	20	50	100
$p(n)$	1	1	2	3	5	7	11	15	22	30	627	~2e5	~2e8

5.2.2 Lucas' Theorem

Let n, m be non-negative integers and p a prime. Write $n = n_k p^k + ... + n_1 p + n_0$ and $m = m_k p^k + ... + m_1 p + m_0$. Then $\binom{n}{m} \equiv \prod_{i=0}^{k} \binom{n_i}{m_i} \pmod{p}$.

5.3 General purpose numbers

5.3.1 Bernoulli numbers

EGF of Bernoulli numbers is $B(t) = \frac{t}{e^t - 1}$ (FFT-able).
$B[0, \ldots] = [1, -\frac{1}{2}, \frac{1}{6}, 0, -\frac{1}{30}, 0, \frac{1}{42}, \ldots]$

Sums of powers:

$$\sum_{i=1}^{n} i^m = \frac{1}{m+1} \sum_{k=0}^{m} \binom{m+1}{k} B_k (n+1)^{m+1-k}$$

Euler-Maclaurin formula for infinite sums:

$$\sum_{i=m}^{\infty} f(i) = \int_m^{\infty} f(x)dx - \sum_{k=1}^{\infty} \frac{B_k}{k!} f^{(k-1)}(m)$$

$$\approx \int_m^{\infty} f(x)dx + \frac{f(m)}{2} - \frac{f'(m)}{12} + \frac{f'''(m)}{720} + O(f^{(5)}(m))$$

5.3.2 Stirling numbers of the first kind
Number of permutations on n items with k cycles.

$$c(n,k) = c(n-1,k-1) + (n-1)c(n-1,k), \ c(0,0) = 1$$
$$\sum_{k=0}^{n} c(n,k)x^k = x(x+1)\dots(x+n-1)$$

$c(8,k) = 8, 0, 5040, 13068, 13132, 6769, 1960, 322, 28, 1$
$c(n,2) = 0, 0, 1, 3, 11, 50, 274, 1764, 13068, 109584, \dots$

5.3.3 Eulerian numbers
Number of permutations $\pi \in S_n$ in which exactly k elements are greater than the previous element. k j:s s.t. $\pi(j) > \pi(j+1)$, $k+1$ j:s s.t. $\pi(j) \geq j$, k j:s s.t. $\pi(j) > j$.

$$E(n,k) = (n-k)E(n-1,k-1) + (k+1)E(n-1,k)$$

$$E(n,0) = E(n,n-1) = 1$$

$$E(n,k) = \sum_{j=0}^{k} (-1)^j \binom{n+1}{j} (k+1-j)^n$$

5.3.4 Stirling numbers of the second kind
Partitions of n distinct elements into exactly k groups.

$$S(n,k) = S(n-1,k-1) + kS(n-1,k)$$

$$S(n,1) = S(n,n) = 1$$

$$S(n,k) = \frac{1}{k!} \sum_{j=0}^{k} (-1)^{k-j} \binom{k}{j} j^n$$

5.3.5 Bell numbers
Total number of partitions of n distinct elements. $B(n) = 1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, \dots$. For p prime,

$$B(p^m + n) \equiv mB(n) + B(n+1) \pmod{p}$$

5.3.6 Labeled unrooted trees
on n vertices: n^{n-2}
on k existing trees of size n_i: $n_1 n_2 \cdots n_k n^{k-2}$
with degrees d_i: $(n-2)!/((d_1-1)!\cdots(d_n-1)!)$

5.3.7 Catalan numbers

$$C_n = \frac{1}{n+1}\binom{2n}{n} = \binom{2n}{n} - \binom{2n}{n+1} = \frac{(2n)!}{(n+1)!n!}$$

$$C_0 = 1, \ C_{n+1} = \frac{2(2n+1)}{n+2}C_n, \ C_{n+1} = \sum C_i C_{n-i}$$

$C_n = 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, \dots$

- sub-diagonal monotone paths in an $n \times n$ grid.
- strings with n pairs of parenthesis, correctly nested.
- binary trees with with $n+1$ leaves (0 or 2 children).
- ordered trees with $n+1$ vertices.
- ways a convex polygon with $n+2$ sides can be cut into triangles by connecting vertices with straight lines.
- permutations of $[n]$ with no 3-term increasing subseq.

5.4 Other

DeBruijnSeq.h
Description: Given alphabet $[0,k)$ constructs a cyclic string of length k^n that contains every length n string as substr.   a6961b, 13 lines

```
vi deBruijnSeq(int k, int n) {
  if (k == 1) return {0};
  vi seq, aux(n+1);
  function<void(int,int)> gen = [&](int t, int p) {
    if (t > n) { // +lyndon word of len p
      if (n%p == 0) FOR(i,1,p+1) seq.pb(aux[i]);
    } else {
      aux[t] = aux[t-p]; gen(t+1,p);
      while (++aux[t] < k) gen(t+1,t);
    }
  };
  gen(1,1); return seq;
}
```

NimProduct.h
Description: Product of nimbers is associative, commutative, and distributive over addition (xor). Forms finite field of size 2^{2^k}. Defined by $ab = \text{mex}(\{a'b + ab' + a'b' : a' < a, b' < b\})$. Application: Given 1D coin turning games G_1, G_2 $G_1 \times G_2$ is the 2D coin turning game defined as follows. If turning coins at $x_1, x_2, \dots, x_m$ is legal in G_1 and $y_1, y_2, \dots, y_n$ is legal in G_2, then turning coins at all positions (x_i, y_j) is legal assuming that the coin at (x_m, y_n) goes from heads to tails. Then the grundy function $g(x,y)$ of $G_1 \times G_2$ is $g_1(x) \times g_2(y)$.
Time: 64^2 xors per multiplication, memorize to speed up.   5afe17, 46 lines

```

MatroidIsect.h
Description: Computes a set of maximum size which is independent in both graphic and colorful matroids, aka a spanning forest where no two edges are of the same color. In general, construct the exchange graph and find a shortest path. Can apply similar concept to partition matroid. M1 should have the slower matroid and M2 the faster matroid.
Usage: MatroidIsect<Gmat,Cmat> M(Gmat(V,ed),Cmat(col),sz(ed)); M.solve();
Time: $\mathcal{O}(GI^{1.5})$ calls to oracles, where G is size of ground set and I is size of independent set.

}
```

PolyInvSimpler.h
Description: computes A^{-1} such that $AA^{-1} \equiv 1 \pmod{x^n}$. Newton's method: If you want $F(x) = 0$ and $F(Q_k) \equiv 0 \pmod{x^a}$ then $Q_{k+1} = Q_k - \frac{F(Q_k)}{F'(Q_k)} \pmod{x^{2a}}$ satisfies $F(Q_{k+1}) \equiv 0 \pmod{x^{2a}}$. Application: if $f(n),g(n)$ are the #s of forests and trees on n nodes then $\sum_{n=0}^{\infty} f(n)x^n = \exp\left(\sum_{n=1}^{\infty} \frac{g(n)}{n!}\right)$.
Usage: vmi v{1,5,2,3,4}; ps(exp(2*log(v,9),9)); // squares v
Time: $\mathcal{O}(N\log N)$. For $N = 5 \cdot 10^5$, inv$\sim$270ms, log $\sim$350ms, exp$\sim$550ms

```
poly inv(poly A, int n) { // Q-(1/Q-A)/(-Q^{-2})

    T ans = 0; F0R(i,sz(v)) ans += v[i]*s[i];
    return ans; } // get p-th term of rec
  T eval(ll p) { assert(p >= 0); return dot(getPow(p)); }
};
```

Integrate.h
Description: Integration of a function over an interval using Simpson's rule, exact for polynomials of degree up to 3. The error should be proportional to dif^4, although in practice you will want to verify that the result is stable to desired precision when epsilon changes.
Usage: quad([](db x) { return x*x+3*x+1; }, 2, 3) //

```
template<class F> db quad(F f, db a, db b) {
```

```
    const int n = 1000;
    db dif = (b-a)/2/n, tot = f(a)+f(b);
    FOR(i,1,2*n) tot += f(a+i*dif)*(i&1?4:2);
    return tot*dif/3;
}
```

IntegrateAdaptive.h
Description: Unused. Fast integration using adaptive Simpson's rule, exact for polynomials of degree up to 5.
Usage: db z, y;
db h(db x) { return x*x + y*y + z*z <= 1; }
db g(db y) { ::y = y; return quad(h, -1, 1); }
db f(db z) { ::z = z; return quad(g, -1, 1); }
db sphereVol = quad(f,-1,1), pi = sphereVol*3/4;   3b316e, 10 lines

```
template<class F> db simpson(F f, db a, db b) {
    db c = (a+b)/2; return (f(a)+4*f(c)+f(b))*(b-a)/6; }
template<class F> db rec(F& f, db a, db b, db eps, db S) {
    db c = (a+b)/2;
    db S1 = simpson(f,a,c), S2 = simpson(f,c,b), T = S1+S2;
    if (abs(T-S)<=15*eps || b-a<1e-10) return T+(T-S)/15;
    return rec(f,a,c,eps/2,S1)+rec(f,c,b,eps/2,S2);
}
template<class F> db quad(F f, db a, db b, db eps = 1e-8) {
    return rec(f,a,b,eps,simpson(f,a,b)); }
```

Simplex.h
Description: Solves a general linear maximization problem: maximize $c^T x$ subject to $Ax \le b, x \ge 0$. Returns -inf if there is no solution, inf if there are arbitrarily good solutions, or the maximum value of $c^T x$ otherwise. The input vector is set to an optimal x (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that $x = 0$ is viable.
Usage: vvd A{{1,-1}, {-1,1}, {-1,-2}};
vd b{1,1,-4}, c{-1,-1}, x;
T val = LPSolver(A, b, c).solve(x);
Time: $\mathcal{O}(NM \cdot \#pivots)$, where a pivot may be e.g. an edge relaxation.
$\mathcal{O}(2^N)$ in the general case.
"template.hpp"   c99f9c, 67 lines

};
```

7.2.1   SqrtDecompton
HLD generally suffices. If not, here are some common
strategies:

- Rebuild the tree after every $\sqrt{N}$ queries.

- Consider vertices with $>$ or $< \sqrt{N}$ degree separately.

- For subtree updates, note that there are $O(\sqrt{N})$ distinct
  sizes among child subtrees of any node.

Block Tree: Use a DFS to split edges into contiguous groups of
size $\sqrt{N}$ to $2\sqrt{N}$.

Mo's Algorithm for Tree Paths: Maintain an array of
vertices where each one appears twice, once when a DFS enters
the vertex (st) and one when the DFS exists (en). For a tree
path $u \leftrightarrow v$ such that st[u]<st[v],

- If u is an ancestor of v, query [st[u],st[v]].

- Otherwise, query [en[u],st[v]] and consider $LCA(u,v)$
  separately.

Solutions with worse complexities can be faster if you optimize
the operations that are performed most frequently. Use arrays
instead of vectors whenever possible. Iterating over an array in
order is faster than iterating through the same array in some
other order (ex. one given by a random permutation) or DFSing
on a tree of the same size. Also, the difference between $\sqrt{N}$ and
the optimal block (or buffer) size can be quite large. Try up to 5x
smaller or larger (at least).

7.3   DFS Algorithms

EulerPath.h
Description: Eulerian path starting at src if it exists, visits all edges
exactly once. Works for both directed and undirected. Returns vector of
{vertex,label of edge to vertex}. Second element of first pair is always -1.
Time: $\mathcal{O}(N + M)$
"template.hpp"   9c222d, 23 lines

```
template<bool directed> struct Euler {
  int N; V<vpi> adj; V<vpi::iterator> its; vb used;
  void init(int _N) { N = _N; adj.rsz(N); }
  void ae(int a, int b) {
    int M = sz(used); used.pb(0);
    adj[a].eb(b,M); if (!directed) adj[b].eb(a,M); }
  vpi solve(int src = 0) {
    its.rsz(N); F0R(i,N) its[i] = begin(adj[i]);
    vpi ans, s{{src,-1}}; // {{vert,prev vert},edge label}
    int lst = -1; // ans generated in reverse order
    while (sz(s)) {
      int x = s.bk.f; auto& it=its[x], en=end(adj[x]);
      while (it != en && used[it->s]) ++it;
      if (it == en) { // no more edges out of vertex
        if (lst != -1 && lst != x) return {};
        // not a path, no tour exists
        ans.pb(s.bk); s.pop_back(); if (sz(s)) lst=s.bk.f;
      } else s.pb(*it), used[it->s] = 1;
    } // must use all edges
    if (sz(ans) != sz(used)+1) return {};
    reverse(all(ans)); return ans;
  }
}
```

```
};
```

SCCT.h
Description: Tarjan's, DFS once to generate strongly connected components in topological order. a, b in same component if both $a \to b$ and $b \to a$ exist. Uses less memory than Kosaraju b/c doesn't store reverse edges.
Time: $\mathcal{O}(N + M)$

a36e0c, 22 lines

```cpp
struct SCC {
  int N, ti = 0; V<vi> adj;
  vi disc, comp, stk, comps;
  void init(int _N){ N = _N, adj.rsz(N);
    disc.rsz(N), comp.rsz(N,-1);}

    int low = disc[x] = ++ti; stk.pb(x);
    each(y,adj[x]) if (comp[y] == -1) // comp[y] == -1,
      ckmin(low,disc[y]?:dfs(y)); // disc[y] != 0 -> in stack
    if (low == disc[x]) { // make new SCC
      // pop off stack until you find x
      comps.pb(x); for (int y = -1; y != x;)
        comp[y = stk.bk] = x, stk.pop_back();
    }
    return low;
  }
  void gen() {
    F0R(i,N) if (!disc[i]) dfs(i);
    reverse(all(comps));
  }
};
```

TwoSAT.h
Description: Calculates a valid assignment to boolean variables a, b, c,... to a 2-SAT problem, so that an expression of the type $(a\|\|b)\&\&(!a\|\|\|c)\&\&(d\|\|\|!b)\&\&...$ becomes true, or reports that it is unsatisfiable. Negated variables are represented by bit-inversions ($\sim x$).
Usage: TwoSat ts;
ts.either(0, ~3); // Var 0 is true or var 3 is false
ts.setVal(2); // Var 2 is true
ts.atMostOne({0,~1,2}); // <= 1 of vars 0, ~1 and 2 are true
ts.solve(N); // Returns true iff it is solvable
ts.ans[0..N-1] holds the assigned values to the vars

"SCC.h"   ff0f3d, 31 lines

      each(e,c) ad(ed[e].f), ad(ed[e].s);
      each(e,c) in[ed[e].f] = in[ed[e].s] = 0;
    }
  }
};
```

MaximalCliques.h
Description: Used only once. Finds all maximal cliques.
Time: $\mathcal{O}\left(3^{N/3}\right)$

f5cd93, 16 lines

```cpp
using B = bitset<128>; B adj[128];
int N;
// possibly in clique, not in clique, in clique
void cliques(B P = ~B(), B X={}, B R={}) {
  if (!P.any()) {
    if (!X.any()) // do smth with R
    return;
  }
  int q = (P|X)._Find_first();
  // clique must contain q or non-neighbor of q
  B cands = P&~adj[q];
  F0R(i,N) if (cands[i]) {
    R[i] = 1; cliques(P&adj[i],X&adj[i],R);
    R[i] = P[i] = 0; X[i] = 1;
```

```
  }
}
```

7.4 Flows
Konig's Theorem: In a bipartite graph, max matching = min vertex cover.

Dilworth's Theorem: For any partially ordered set, the sizes of the max antichain and of the min chain decomposition are equal. Equivalent to Konig's theorem on the bipartite graph (U, V, E) where $U = V = S$ and (u, v) is an edge when $u < v$. Those vertices outside the min vertex cover in both U and V form a max antichain.

Dinic.h
Description: Fast flow. After computing flow, edges $\{u,v\}$ such that $lev[u] \neq -1$, $lev[v] = -1$ are part of min cut. Use reset and rcap for Gomory-Hu.
Time: $\mathcal{O}\left(N^2M\right)$ flow, $\mathcal{O}\left(M\sqrt{N}\right)$ bipartite matching

"template.hpp"   b7b370, 38 lines

```cpp
struct Dinic {
  using F = ll; // flow type
  struct Edge { int to; F flo, cap; };
  int N; V<Edge> eds; V<vi> adj;
  void init(int _N) { N = _N; adj.rsz(N), cur.rsz(N); }
  void ae(int u, int v, F cap, F rcap = 0) { assert(min(cap,
    ↪rcap) >= 0);
    adj[u].pb(sz(eds)); eds.pb({v,0,cap});
    adj[v].pb(sz(eds)); eds.pb({u,0,rcap});
  }
  vi lev; V<vi::iterator> cur;
  bool bfs(int s, int t) { // level = shortest distance from
    ↪source
    lev = vi(N,-1); F0R(i,N) cur[i] = begin(adj[i]);
    queue<int> q({s}); lev[s] = 0;
    while (sz(q)) { int u = q.ft; q.pop();
      each(e,adj[u]) { const Edge& E = eds[e];
        int v = E.to; if (lev[v] < 0 && E.flo < E.cap)
          q.push(v), lev[v] = lev[u]+1;
      }
    }
    return lev[t] >= 0;
  }
  F dfs(int v, int t, F flo) {
    if (v == t) return flo;
    for (; cur[v] != end(adj[v]); cur[v]++) {
      Edge& E = eds[*cur[v]];
      if (lev[E.to]!=lev[v]+1||E.flo==E.cap) continue;
      F df = dfs(E.to,t,min(flo,E.cap-E.flo));
      if (df) { E.flo += df; eds[*cur[v]^1].flo -= df;
        return df; } // saturated >=1 one edge
    }
    return 0;
  }

7.5 Matching

Hungarian.h
Description: Given J jobs and W workers ($J \leq W$), computes the minimum cost to assign each prefix of jobs to distinct workers.
@tparam T a type large enough to represent integers on the order of J * max(—C—) @param C a matrix of dimensions JxW such that C[j][w] = cost to assign j-th job to w-th worker (possibly negative)
@return a vector of length J, with the j-th entry equaling the minimum cost to assign the first (j+1) jobs to distinct workers
Time: $\mathcal{O}\left(J^2 W\right)$

LCT.h

Description: Link-Cut Tree. Given a function $f(1 \ldots N) \to 1 \ldots N$, evaluates $f^b(a)$ for any a, b. sz is for path queries; sub, vsub are for subtree queries. x->access() brings x to the top and propagates it; its left subtree will be the path from x to the root and its right subtree will be empty. Then sub will be the number of nodes in the connected component of x and vsub will be the number of nodes under x. Use makeRoot for arbitrary path queries.
Usage: FOR(i,1,N+1)LCT[i]=new snode(i); link(LCT[1],LCT[2],1);
Time: $\mathcal{O}(\log N)$

```
typedef struct snode* sn;

LineHull.h

Description: `lineHull` accepts line and ccw convex polygon. If all vertices in poly lie to one side of the line, returns a vector of closest vertices to line as well as orientation of poly with respect to line (± 1 for above/below). Otherwise, returns the range of vertices that lie on or below the line. `extrVertex` returns the point of a hull with the max projection onto a line.
Time: $\mathcal{O}(\log N)$

```

HalfPlaneIsect.h

Description: Returns vertices of half-plane intersection. A half-plane is the area to the left of a ray, which is defined by a point p and a direction dp. Area of intersection should be sufficiently precise when all inputs are integers with magnitude $\leq 10^5$. Intersection must be bounded. Probably works with floating point too (but EPS might need to be adjusted?).
Time: $\mathcal{O}(N \log N)$

`"AngleCmp.h"`   18f712, 52 lines

```

Hull3D.h

Description: Incremental 3D convex hull where not all points are coplanar. Normals to returned faces point outwards. If coordinates are ints at most B then T should be large enough to support ints on the order of B^3. Changes order of points. The number of returned faces may depend on the random seed, because points that are on the boundary of the convex hull may or may not be included in the output.
Time: $\mathcal{O}(N^2)$, $\mathcal{O}(N \log N)$

```                                                                      5f4f0e, 91 lines

Various (10)

10.1 Dynamic programming
When doing DP on intervals:
$$a[i][j] = \min_{i<k<j}(a[i][k] + a[k][j]) + f(i,j),$$ where the (minimal) optimal k increases with both i and j,

- one can solve intervals in increasing order of length, and search $k = p[i][j]$ for $a[i][j]$ only between $p[i][j-1]$ and $p[i+1][j]$.

- This is known as Knuth DP. Sufficient criteria for this are if $f(b,c) \le f(a,d)$ and $f(a,c) + f(b,d) \le f(a,d) + f(b,c)$ for all $a \le b \le c \le d$.

- Consider also: LineContainer (ch. Data structures), monotone queues, ternary search.

CircularLCS.h
Description: Used only twice. For strs A, B calculates longest common subsequence of A with all rotations of B
Time: $\mathcal{O}(|A| \cdot |B|)$ db21cf, 26 lines

```cpp
int circular_lcs(str A, str B) {
  B += B;
  int max_lcs = 0;
  V<vb> dif_left(sz(A)+1,vb(sz(B)+1)), dif_up(sz(A)+1,vb(sz(B)
    ↪+1));
  auto recalc = [&](int x, int y) { assert(x && y);
    int res = (A.at(x-1) == B.at(y-1)) |
      dif_up[x][y-1] | dif_left[x-1][y];
    dif_left[x][y] = res-dif_up[x][y-1];
    dif_up[x][y]   = res-dif_left[x-1][y];
  };
  FOR(i,1,sz(A)+1) FOR(j,1,sz(B)+1) recalc(i,j);
  F0R(j,sz(B)/2) {
    // 1. zero out dp[.][j], update dif_left and dif_right
    if (j) for (int x = 1, y = j; x <= sz(A) && y <= sz(B); ) {
      int pre_up = dif_up[x][y];
      if (y == j) dif_up[x][y] = 0;
      else recalc(x,y);
      (pre_up == dif_up[x][y]) ? ++x : ++y;
    }
    // 2. calculate LCS(A[0:sz(A)),B[j:j+sz(B)/2))
    int cur_lcs = 0;
    FOR(x,1,sz(A)+1) cur_lcs += dif_up[x][j+sz(B)/2];
    ckmax(max_lcs,cur_lcs);
  }
  return max_lcs;
}
```

SMAWK.h
Description: Given negation of totally monotone matrix with entries of type D, find indices of row maxima (their indices increase for every submatrix). If tie, take lesser index. f returns matrix entry at (r, c) in $O(1)$. Use in place of divide & conquer to remove a log factor.
Time: $\mathcal{O}(R + C)$, can be reduced to $\mathcal{O}(C(1 + \log R/C))$ evaluations of f 0a9abb, 25 lines

```cpp
template<class F, class D=ll> vi smawk (F f, vi x, vi y) {
  vi ans(sz(x),-1); // x = rows, y = cols
  #define upd() if (ans[i] == -1 || w > mx) ans[i] = c, mx = w
```

```cpp
  if (min(sz(x),sz(y)) <= 8) {
    F0R(i,sz(x)) { int r = x[i]; D mx;
      each(c,y) { D w = f(r,c); upd(); } }
    return ans;
  }
  if (sz(x) < sz(y)) { // reduce subset of cols to consider
    vi Y; each(c,y) {
      for (;sz(Y);Y.pop_back()) { int X = x[sz(Y)-1];
        if (f(X,Y.bk) >= f(X,c)) break; }
      if (sz(Y) < sz(x)) Y.pb(c);
    } y = Y;
  } // recurse on half the rows
  vi X; for (int i = 1; i < sz(x); i += 2) X.pb(x[i]);
  vi ANS = smawk(f,X,y); F0R(i,sz(ANS)) ans[2*i+1] = ANS[i];
  for (int i = 0, k = 0; i < sz(x); i += 2){
    int to = i+1 < sz(ans) ? ans[i+1] : y.bk; D mx;
    for(int r = x[i];;++k){
      int c = y[k]; D w = f(r,c); upd();
      if (c == to) break; }
  }
  return ans;
};
```

10.2 Debugging tricks

- `signal(SIGSEGV, [](int) { _Exit(0); });` converts segfaults into Wrong Answers. Similarly one can catch SIGABRT (assertion failures) and SIGFPE (zero divisions). _GLIBCXX_DEBUG violations generate SIGABRT (or SIGSEGV on gcc 5.4.0 apparently).

- `feenableexcept(29);` kills the program on NaNs (1), 0-divs (4), infinities (8) and denormals (16).

10.3 Optimization tricks
10.3.1 Bit hacks

- `x & -x` is the least bit in x.

- `for (int x = m; x; ) { --x &= m; ... }` loops over all subset masks of m (except m itself).

- `c = x&-x, r = x+c; (((r^x) >> 2)/c) | r` is the next number after x with the same number of bits set.

- `F0R(b,k) F0R(i,1<<K) if (i&1<<b) D[i] += D[i^(1<<b)];` computes all sums of subsets.

10.3.2 Pragmas

- **#pragma** GCC optimize ("Ofast") will make GCC auto-vectorize for loops and optimizes floating points better (assumes associativity and turns off denormals).

- **#pragma** GCC target ("avx,avx2") can double performance of vectorized code, but causes crashes on old machines. Also consider older **#pragma** GCC target ("sse4").

- **#pragma** GCC optimize ("trapv") kills the program on integer overflows (but is really slow).

10.4   Other languages

Python3.py
Description: Python review.

40 lines

```python
from math import *
import sys, random
def nextInt():
  return int(input())
def nextStrs():
  return input().split()
def nextInts():
  return list(map(int,nextStrs()))
